Adolescents have the unhealthiest diets of all age groups [1-4], and most adolescents do not meet the national guidelines for physical activity (PA), spending too much time being sedentary [4]. These behaviours can lead to obesity and increase the risk of a range of non-communicable diseases (NCDs) such as diabetes, cancer, and heart disease in later life [5-7]. There is an additional challenge with adolescents as they are in a developmental stage where a sense of autonomy develops and many adolescents are resistant to interventions that they feel impede their independence [8]. In response to the poor health behaviours of adolescents, as well as the unique challenges associated with changing the behaviours of this group, a range of interventions have been developed and tested. Many of these focussed on giving diet or PA education and are often school-based [9-13]. In the context of the studies included in this review, education components include classroom-based lectures, face-to-face provision of information, or teaching through printed materials or digital media. Other interventions for improving adolescents' health behaviours are community-based [14-16] and may include parental or family involvement [17, 18]. Recently, however, there has been an explosion in the use of digital interventions to improve health behaviours.

In the last few years, internet usage and smartphone ownership have seen a worldwide increase; approximately 90% of adults in the US and UK use the internet and 91% of millennials in these countries own smartphones [19]. US data from 2015 suggested that 92% of adolescents accessed the internet daily, with 24% saying that they were online almost constantly [20]. In addition, the advent of fitness trackers such as Fitbit® has introduced a new platform for motivating people to be physically active, although evidence for their effectiveness is limited [21]. Digital means of communication are considered to be acceptable to adolescents, and a review of text messaging interventions for preventing obesity in adolescents confirmed this [22]. Given the nearly universal accessibility of digital media in high income countries, as well as the affordability and scalability of interventions using these platforms, it is not surprising that there is now considerable interest in developing digital interventions for behaviour change.

To develop effective interventions that result in sustained change to the health behaviours of adolescents, it is necessary to understand which elements of such interventions are effective. A systematic review of digital interventions for increasing PA in adolescents, published in 2011, found that such interventions could produce small but significant increases in PA, and that they were most effective when combined with other delivery methods such as face-to-face contact [23]. Since then, there has been a rapid change in the way adolescents use digital media, coinciding with an increase in the number of digital interventions that have been developed. For example, social media platforms such as Snapchat[24] and Instagram [25] have been launched since 2010, and are widely used amongst young people. In addition, the popular running app 'Zombies, Run!' was launched in 2012 and gained record-breaking popularity [26]. The dynamic nature of the digital world and the ways in which it is used by adolescents mean that up-to-date reviews of evidence are required to understand the factors that influence the effectiveness of digital interventions for improving the diet and PA behaviours of adolescents.

More recently, Lappan et al. reviewed RCTs of interventions that included text messages, websites or smartphone apps that aimed to improve diet, physical activity or BMI in children or adolescents [27]. They found that digital platforms often supported improvements in diet and physical activity, and sometimes in body weight or BMI. The authors also concluded that it was important to use a behaviour change theory to design digital interventions for improving health behaviours. In our review, we contributed to the growing body of knowledge on digital interventions for improving the health behaviours of adolescents. Our search was not limited to RCTs, or to any specific form of digital intervention. We aimed to identify specific intervention components that characterise the more successful interventions.

As well as assessing the effectiveness of these interventions with regard to improving diet and PA, it is imperative to understand the cost-effectiveness of each approach [28]. Evaluation of cost-effectiveness assesses whether an intervention is a good use of resources and, in healthcare, can be

calculated as cost per quality-adjusted life year (QALY). We aimed to take a very broad definition and, where they were available, would include any data about the cost of a given intervention. Digital platforms are often regarded as representing a cost-effective resource for intervention [29, 30]. Healthcare interventions delivered digitally have been found to be cost-effective [31, 32], but data for cost-effectiveness of behaviour change interventions are lacking [32]. Therefore, this review aimed to collate cost-effectiveness data presented in included publications

## **Aims**

The aim of this review was to synthesise evidence on the effectiveness of digital interventions to improve diet quality and increase PA in adolescents, to identify the most effective intervention components and to assess the cost-effectiveness of these interventions.

The following questions were addressed:

- 1) How can digital interventions be used to improve quality of diet and increase physical activity in adolescents, and which intervention features characterise successful interventions?
- 2) How cost-effective are such interventions?

## **Methods**

### *Study selection*

The methods for this systematic review followed best practice guidelines for the conduct of systematic reviews, developed by the Centre for Reviews and Dissemination (CRD) [33]. First, a search was carried out in November 2015 by an information specialist using electronic databases MEDLINE, PsycINFO, CINAHL, PubMed Central, Embase, ERIC, the NHS EED and CENTRAL with no restrictions on date of publication (from earliest available through November 2015). A combination of MeSH and free text terms were selected in order to find publications pertaining to adolescent health behaviours, nutrition, PA, and specifically intervention studies that aimed to improve them. The complete search strategy is in **Appendix A**.

After removing duplicates, this search led to the identification of 6,791 publications, which were independently screened by two researchers (TR and CJ) who compared the titles and abstracts against the inclusion and exclusion criteria listed in **Table 1**. A total of 31 publications reporting on 26 studies met review inclusion criteria (**Figure 1**). Reference lists of included studies were screened for additional publications that might address review questions. In addition, experts in the field were consulted to identify further relevant publications, which resulted in one additional publication so the review included a total of 32 publications reporting on 26 studies.

Studies were selected if they met inclusion criteria based on study design, target population, intervention type and study outcomes. All included studies described an intervention study using an experimental or quasi-experimental design, with or without a control group. Given the relative paucity of studies, we took a decision to include studies without a control group despite the increased risk of bias, but took account of this bias in the narrative synthesis. Observational studies were not included. Included interventions were aimed at adolescents, using the WHO definition of 10-19 years, and were conducted in any setting. The interventions described were digital, which could include use of websites, mobile phones or smartphones, email, personal digital assistants, social media or any multicomponent intervention that included these. Only studies that reported change from baseline in a dietary and/or PA behaviour were included.

#### *Data extraction and quality assessment*

Data were extracted using a form designed to capture the key content of each study. Concurrent with data extraction, a quality assessment was applied to each study. For this, a quality rubric was designed according to the quality assessment criteria described by the CRD [33]. The checklist was tailored to this review and aimed to assess risk of bias resulting from study design, randomisation, blinding, selection, attrition, assessment, intervention fidelity, analysis and handling of confounding. Risk of bias scores ranged from -7 to +5 and level of risk of bias as presented in **Table 4** was classified according to these scores. Studies with a score between -2 and +2 were

categorised as having a medium risk of bias. Scores below -2 and above +2 were determined to have a low and high risk of bias respectively. The process of data extraction and quality assessment was performed by a single researcher (TR), and a second researcher (CJ) independently reviewed one in three studies (n=9) and there was good agreement between the two researchers. Quality scoring of all studies is presented in **Appendix B**.

### *Data synthesis*

Review findings are reported in accordance with PRISMA guidelines [34] and a meta-analysis was not possible due to considerable heterogeneity in study design, study quality, intervention design, and study population [33].. Summary tables were produced describing the characteristics of included studies, their results and quality assessment (**Tables 3, 4**). In both tables, studies were grouped by the primary type of digital medium used to deliver the intervention. These groups were determined after reviewing all studies, and included website interventions, text message interventions, games and apps, email interventions, social media interventions and multi-component interventions that included a digital element,. If an intervention used multiple digital elements, it was grouped according to the element whose aim was to effect behaviour change rather than, for example, to collect data or act as a reminder. Within each group, studies were listed in chronological order by date of publication.

Once compiled, tables were used to examine the effectiveness of the various types of intervention in improving dietary and PA behaviours of adolescents. As the studies were grouped by type of digital platform, this factor was closely examined as a first step. Individual intervention features were also analysed to determine which of these were most often associated with efficacy, and in what conditions. Here, all of the features of each intervention were listed in **Table 3**. Many of these, such as goal-setting, appeared in multiple studies allowing for comparison of studies that included the same component. Other features were unique to a particular study and these were also

listed in the table. Data about participant engagement were also examined. Data related to cost-effectiveness, if available, were also assessed.

## Results

The results of this systematic review are presented as a narrative synthesis. Of the 26 included studies, more than half (n=15) were website interventions, four were delivered via text message, three were games or apps, one was delivered via email, one used social media and three were multi-component interventions. Two studies reported dietary outcomes only, ten reported PA outcomes, and 15 reported results for both diet and PA. The earliest study was published in 2004, with 21 of the 27 studies being published since 2010. The majority of studies were targeted at a general population of adolescents (age 10-19) and five were targeted at a specific at-risk population. There was considerable variation in the risk of bias between studies, but selection bias and handling of confounding most consistently fell into the high risk category. None of the 26 included studies used random sampling and one study adequately adjusted for confounding. A summary table of bias scoring is in **Appendix B**. The results for intervention effectiveness are grouped by digital platform and described below.

### *Website interventions (n = 15)*

Ten of the 15 website intervention studies were randomised controlled trials and only one study did not use a control group. Despite this, most of the studies had a medium or high risk of bias, with only two of the 15 website intervention studies being rated as having a low risk. Details about trial design are presented in **Table 3** and risk of bias scores are shown in **Table 4**. A summary of the outcomes of all website intervention trials is presented in **Table 2**. Eleven of the 15 interventions that were delivered via websites assessed both dietary and PA outcomes. Two of these studies found no significant improvements in diet or PA [35, 36]. Four of these 11 had inconclusive results; in two, the main reason was the lack of a control group [37, 38] and in one, the study had a medium risk of bias and only reported results in line graphs, requiring some interpretation [39]. Here, a

website and counselling intervention was trialled with obese African American girls and one obese parent. Both groups showed a significant decrease in overeating, and the intervention group showed a decrease in fattening foods that was sustained to 18 months, but not 24 months. The final study with inconclusive results had a low risk of bias. This Dutch study tested the effectiveness of a computer-tailored intervention that consisted of health information, an assessment of behaviour, tailored feedback and an option to set a health goal. There were improvements in some dietary behaviours at four months post-intervention, but none were sustained at two years [40]. For PA, there was a significant decrease in step count from baseline amongst the intervention group, but a subgroup analysis showed a significant increase in participation in sport outside of school. Due to these mixed results, it cannot be concluded that this intervention was either effective or ineffective.

Five of the 11 website interventions that targeted both diet and PA resulted in significant improvements, and for one of these, the only significant result was for sedentary behaviour. This study had a medium risk of bias and tested a website intervention that was targeted at patients of a diabetes clinic in America [41]. The website provided nutrition education and included weekly challenges, goal-setting, skill-building, a reward system and feedback. Participants were also encouraged to use a pedometer for self-monitoring. This study showed a significant decrease in sedentary behaviour of 2 hours per day at 6 months and 12 months. There was no change in % calories from fat or servings of fruit and veg per 1000 calories.

Four website interventions resulted in significant improvements for both diet and PA, and one had a high risk of bias. This consisted of eight 40-minute educational sessions delivered via Blackboard.com [42]. The other three had a medium risk of bias. The first of the medium-risk studies was targeted at Chinese-American adolescents and their parents [43]. Website content was tailored to participants' stage of change and aimed to increase self-efficacy. Parents were given three short coaching sessions to support their children. At the end of the intervention, there was an increase in fruit and vegetable intake as well as in PA and both changes were sustained at eight months. The

second medium risk study was an intervention targeted at American adolescents and used a website that provided information about nutrition and PA, videos, recipes and a blog [44]. Participants were also asked to set one goal per week. At the end of the eight-week study, the intervention group showed a significant increase in vegetable consumption. Both the intervention and the control groups showed a highly significant increase in PA. Thirdly, an American study trialled a Boy Scout badge programme with a physical activity intervention arm and a dietary intervention arm, which were compared. The study did not include a control group. Groups received 'mirror-image' website interventions that employed goal-setting and rewarded those who met their goals with a badge [45, 46]. This trial showed only short-term (1 month) seasonal increases in exercise amongst the group that received the PA intervention. This group also showed a significant increase in low-fat vegetable consumption at 6 months compared to those who received the dietary intervention.

Three of the website interventions aimed to increase PA only. One was a part of the HELENA study, set in Austria, Belgium, Greece, Germany and Sweden, and had a medium risk of bias [47, 48]. This website collected data about physical activity behaviours and psychological determinants, and provided tailored advice based on this. This study showed significant increases in some measures of PA (cycling for transportation, moderate activity in leisure time, vigorous activity in leisure time and total moderate and vigorous physical activity). The other two PA interventions employed self-monitoring via accelerometers and websites that allowed for self-monitoring and provided support. The first had a medium risk of bias and included low active adolescents in the Netherlands [49]. This study showed a relative decrease in sedentary behaviour. The second was targeted at American adolescents and had a low risk of bias [50]. Over the study period, those using the activity meter and website showed a level of PA that was higher than those using the activity meter alone.

One trial targeted improvement of dietary behaviours only. This trial was another part of the HELENA study mentioned above, but focused on diet rather than PA. Similar to the PA programme,

the website collected information via baseline survey about dietary behaviours and provided tailored advice. This intervention had a high risk of bias and showed a small, but not sustained, decrease in dietary fat [51].

#### *Text message interventions*

Of the four text message interventions, three aimed to increase PA and one focussed on dietary behaviours. The dietary intervention used a text message fruit and vegetable diary along with a nutrition education component, and had a high risk of bias. The text message intervention did not have a significant effect, but the intervention as a whole with nutrition lessons did show a significant increase in fruit and vegetable consumption [52]. Another with a high risk of bias was a PA intervention based in Hong Kong that had a website element and also sent text messages from a 'virtual friend' [53]. There was a significant increase in PA from baseline in the intervention group, and engagement with the text message component was much better than with the website.

The other two text message interventions had a medium risk of bias and aimed to increase PA. The first was targeted at adolescents with type 1 diabetes in New Zealand, and consisted of pedometers and weekly text messages [54]. This intervention did not show any significant effects for PA. The second was set in England, and the majority (70%) of participants were girls aged 16-19 [55]. It compared the effectiveness of 'affective' text messages (highlighting the way exercise can make a person feel) against 'instrumental' text messages (highlighting the instrumental gains of regular exercise, such as maintaining a healthy weight). Here, there was a statistically significant increase in reported PA amongst those who were inactive at baseline for the affective text message group.

#### *Games and Apps*

Three studies reported on gamified interventions, and all of them had a medium risk of bias. One was based in Canada and targeted patients of an endocrinology clinic [56]. This intervention consisted of a cycling video game attached to a stationary bike and used listening to music whilst riding the stationary bike as a control condition. Here, the control arm showed significantly better

attendance and time spent doing vigorous activity than the intervention condition. It is not clear from the publication why listening to music may have led to better adherence than a video game. The second gamified intervention was based in America and consisted of two video games that aimed to increase knowledge about energy balance [57]. The only significant result was an increase in consumption of fruit by 0.05 pieces per day compared to a decrease in consumption amongst control participants. The third was set in New Zealand and compared two popular PA apps against a control group, where participants were simply given the app and asked to use it three times per week [58]. Here, neither the 'Zombies, Run! 5k training app' nor 'Get Running' showed any significant effects for outcomes of PA in adolescents, although the sample size for this study was very small (n=51).

#### *Email-delivered intervention*

There was one intervention that used email to promote fruit and vegetable consumption and PA amongst American girls age 15-17 [59]. This study had a high risk of bias, and is the earliest study in this review, being published in 2004. This intervention did not show any significant changes to dietary or PA behaviours at one-year follow-up.

#### *Social media intervention*

One study used Facebook as the primary mode of delivery [60]. This was a low risk of bias study conducted in America, and aimed to increase PA amongst adolescents who were not meeting guidelines. The Facebook page was open to participants and a parent, and provided informational content and weekly private messages to encourage exercise. While the intervention showed a significant increase in self-reported leisure-time PA, there were no significant results for total PA as measured by accelerometer.

#### *Multi-component interventions with a digital element*

Three multi-component interventions including a digital element were conducted in Australian secondary schools. All aimed to improve diet and PA in adolescents who were from areas of lower socioeconomic status. The schools ran programmes that included a number of different non-digital components as well as a digital element. While these interventions were not primarily digital, we took the decision to include them in this review as the digital element of each study was a particular focus to the researchers and they reported on use of these components specifically. Non-digital intervention components included nutrition lessons, parental involvement, sport sessions and self-monitoring. The first study included emails for additional support, the second text messaging, and the third used a smartphone app and website to support behaviour change.

The intervention that included emails showed a significant increase in step count among those who were classified as 'low active' at baseline[61]. This was a high risk of bias study, while the other two had a medium risk. The intervention that included text messaging, and was targeted at girls, did not show any significant improvements in diet or PA [9, 62-64]. The intervention that used a smartphone app and was targeted at boys showed a significant reduction in sweetened beverage consumption only [65], with 63% reporting using the app.

### *Features of effective interventions*

Most (n=22) interventions included diet or PA education, and eight of these resulted in a significant improvement in at least one behaviour [39, 41, 42, 44, 65-68]. Educational elements generally consisted of providing information about the importance of healthy behaviours as well as instruction on how to eat a healthy diet or do enough physical activity. One study showed that a nutrition education element alone resulted in a significant improvement in diet while additional intervention components did not provide further benefit [52]. Some studies with educational elements did not show significant results, or were inconclusive [9, 11, 36, 40, 60], but findings of this review suggest that health education is a potentially valuable component for interventions aimed at improving

health behaviours of adolescents. This may be delivered through a range of media including websites, tailored advice pages, classroom education, or social media.

Goal-setting and self-monitoring were very common components of digital interventions, and these two elements appeared to be most effective when paired. A total of 11 studies used goal-setting, and 14 used self-monitoring; of these, six interventions used both. Crucially, almost all the interventions that included goal setting showed a significant improvement in at least one measure of diet [40, 52, 57, 69], physical activity [41, 49] or both [44, 65, 68]. Self-monitoring was less effective without goal setting [9, 36, 54, 70].

Parental or family involvement was also an important factor in some of the interventions. Most interventions that included this showed some significant improvement in behaviour [10, 38, 39, 41, 43, 60, 65]. However, in interventions where parents were supposed to participate, but did not, there was little intervention effect [9, 11, 57, 67]. In addition to parental engagement, data on participants' engagement with the intervention can provide useful insight into the ways in which behaviour change can be supported. Of the 26 studies included in this review, only four did not report any data on implementation or engagement [38, 42, 55, 57]. For all other studies, available process data are reported in **Table 4**. Due to the variation in data reported and in intervention components, generalisations about engagement and implementation could not be drawn.

### *Cost effectiveness*

None of the studies included a cost-effectiveness analysis or any discussion about the cost of the interventions.

## **Discussion**

Despite the recent popularity in using digital media to improve dietary and PA behaviours, little is known about their effectiveness amongst adolescents. This review has found some evidence that website interventions can effect diet and physical activity behaviour change amongst adolescents.

However, these changes are often not sustained in the medium or long term. This may be partially due to the variability in engagement with interventions, as shown in **Table 4**. While implementation and engagement were not consistently reported, a number of studies published some data about acceptability or use of the digital intervention and this variation was sometimes related to intervention effectiveness [39, 45, 46]. There is a marked lack of evidence for other digital approaches to behaviour change, including text messages, email, smartphones and social media. Despite these gaps, this review showed that particular intervention features, namely health education, goal setting, self-monitoring and targeting to specific populations, can lead to improved diet and physical activity behaviours in adolescents.

#### *Effectiveness of digital interventions for improving diet and physical activity behaviours of adolescents*

This review showed that digital interventions can be effective in improving the diet and physical activity behaviours of adolescents, although these changes are often not sustained in the longer term. The largest evidence base exists for website-delivered interventions. Regarding other digital media, there is much interest in developing smartphone apps for changing health behaviours. As this is a new area, there is a paucity of evidence for their effectiveness and this review did not find any significant results for app interventions. However, one of the school-based multicomponent interventions in Australia that included a smartphone app did find a significant reduction in sweetened beverage consumption [65]. We cannot draw conclusions about text messages or emailing because there were few intervention studies that employed these means of communication and most were ineffective at changing behaviours.

#### *Features of effective interventions*

Whatever the digital platform, the evidence from this review suggests that there are components that most often characterise effective digital interventions for health behaviour change in adolescents. Firstly, while educating adolescents using a range of methods on the importance of

good diet and PA habits is not enough to change behaviour, it is an important element of effective interventions. It is also clearly beneficial to encourage adolescents to set specific diet or PA goals and to provide a means by which progress can be monitored. Examples of approaches to achieving this are pedometers, food diaries, exercise logs, and weight loss trackers.

A component that was sometimes associated with significant improvements in diet and/or PA was parental involvement. This agrees with the findings of a systematic review conducted in 2014 on interventions to prevent childhood obesity. In that review, Kelishadi et al concluded that familial involvement was amongst the key intervention components that encouraged significant improvement in children's health behaviours [71]. As discussed above, most interventions that included a parental element showed significant improvement, but in cases where parents did not participate, their adolescent children failed to improve their health behaviours. Therefore, intervention design might consider whether it is likely that the target population could benefit from an additional component aimed at adolescents' parents.

### *Cost-effectiveness*

In developing public health interventions, it is important to consider their cost-effectiveness, so this review aimed to extract and analyse cost data from included studies. Unfortunately, cost-effectiveness is often not assessed in any formal way, and none of the 32 publications included in this review reported cost-effectiveness data on their interventions. Furthermore, the heterogeneity of interventions precludes the synthesis of general conclusions about cost because most interventions included other components in addition to the digital platform and because some studies required participants to have their own technology while others provided the necessary devices. This is a clear gap in the literature, and should be addressed in future public health intervention trials. As digital platforms are assumed to provide an opportunity for low-cost, scalable interventions, this is especially relevant.

### *Strengths and limitations*

This review followed established guidance on the conduct of systematic reviews [33]. The literature search was comprehensive, and designed to capture a wide range of digital interventions for improving the health behaviours of adolescents. The screening process was undertaken by two independent researchers, and final lists were compared to reduce the chance of omitting any relevant studies. Data extraction was rigorous and used a data extraction form that was piloted at the start of the review. Similarly, quality criteria were clearly defined from the outset, so the quality assessment process was consistent and transparent. Only one reviewer carried out all data extraction, but in order to reduce bias a second reviewer assessed one in three studies and there was agreement about results and conclusions in every case.

There was considerable heterogeneity between studies included in this review. While they could be grouped reasonably well by digital media platform, there was still variation within these groups with regards to intervention content, duration, intensity, setting, target population and outcome measures. The heterogeneity of studies meant that a meta-analysis was not feasible. However, a narrative synthesis was carried out, grouping interventions by digital platform, and then examining the frequencies of key features of each intervention to look for trends.

While most included studies were randomised controlled trials, the majority (19 of 27) had a medium to high risk of bias overall. Common sources of bias were small sample size, participant selection bias and poor handling of confounding factors in data analysis. A source of bias in many systematic reviews is publication bias, which results from the fact that studies with positive findings are more likely to be published than studies that do not show an effect. For this review, only published studies were included, but consultation with experts did not reveal any unpublished works that should be included.

### *Conclusions*

Digital media are widely accessed by adolescents, and may represent a scalable and inexpensive opportunity for engaging this group in behaviour change. The findings of this review suggest that

digital interventions that include health education, goal-setting, self-monitoring, and parent involvement can produce significant improvements in the dietary and PA behaviours of adolescents. This is particularly the case with interventions using websites as this platform represented 15 of the 27 included studies. There is less evidence for the effectiveness of other digital platforms such as apps, text messages and social media, despite the constantly growing number of interventions using these resources, due to the paucity of well-designed trials of these interventions. Smartphone-based interventions are widely accessible and low-cost, and make use of resources already used by most adolescents. Therefore, it is important that more high-quality trials be conducted and published in the academic literature, and apps that have already been developed should be formally trialled in order to inform the development of future behaviour change interventions.

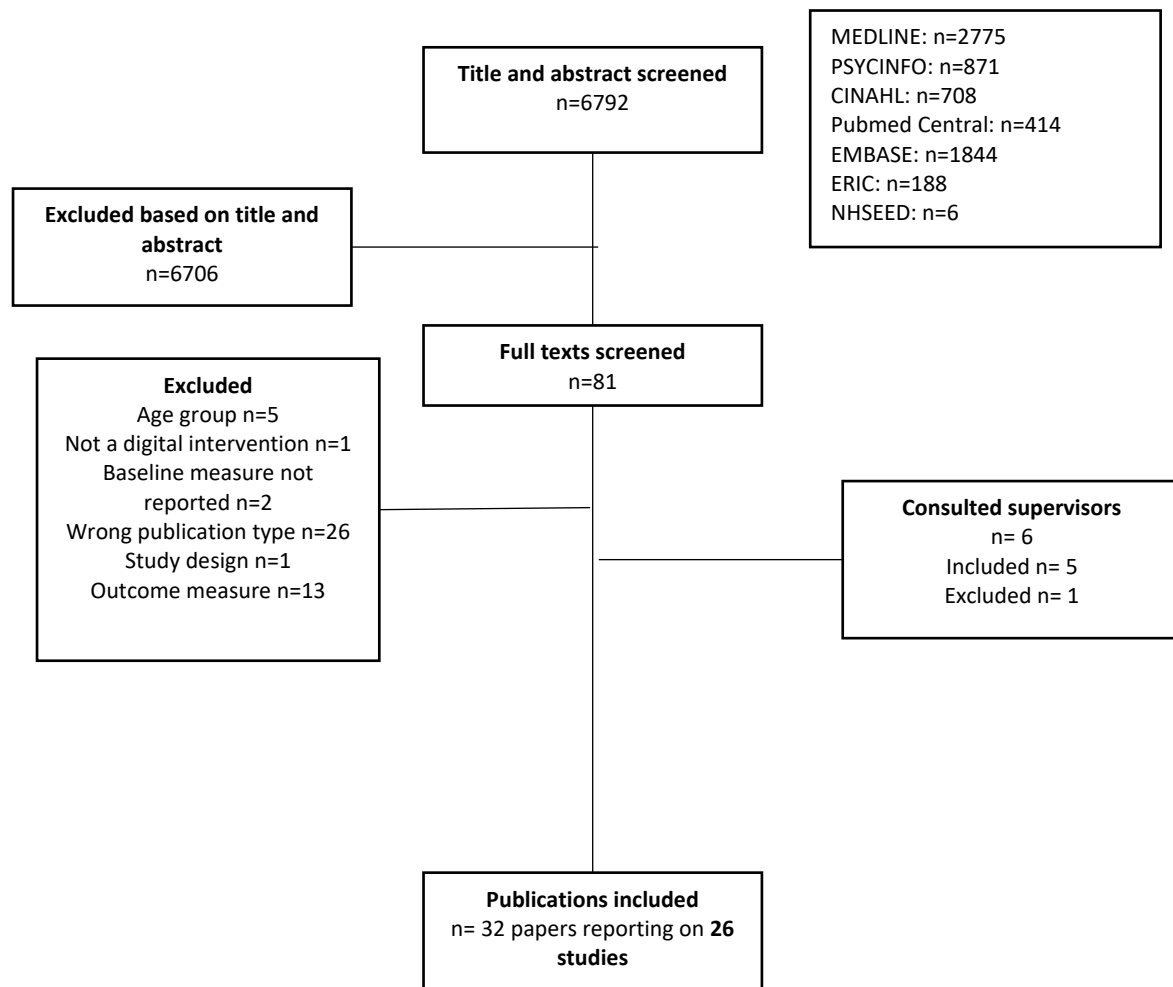

Figure 1 Flow diagram of study

Table 1: Inclusion and exclusion criteria

	Criteria	Justification
Inclusion	<ul style="list-style-type: none"> <li>Interventions with and without a control group</li> <li>Participants fall within the specified age range of 10-19</li> <li>Digital interventions including smartphone applications, websites, text messaging, social media, email and PDA use</li> <li>Studies that measure a diet or PA outcome at two or more time points, and where one measurement is a baseline measure</li> <li>Any setting</li> <li>Any population of adolescents</li> </ul>	<ul style="list-style-type: none"> <li>While lack of a control increases bias, excluding these papers would result in a less comprehensive review</li> <li>This review is focused on adolescents</li> <li>This review aims to determine the effectiveness of digital interventions specifically</li> <li>This review is looking at interventions that effect a change, so baseline and follow-up measures are required</li> <li>In order to be as comprehensive as possible, inclusion is not limited by setting or population group</li> </ul>
Exclusion	<ul style="list-style-type: none"> <li>Observational studies</li> <li>Studies that do not report change in any dietary or PA outcomes</li> <li>Interventions that do not include a digital component</li> <li>Papers published in a language other than English</li> <li>Interventions that aimed to treat disordered eating</li> </ul>	<ul style="list-style-type: none"> <li>This is a review of interventions</li> <li>Change in diet and PA are the primary outcome measures</li> <li>This review aims to determine the effectiveness of digital interventions</li> <li>Translation resources are not available</li> <li>Promotion of healthy diet and adequate levels of physical activity requires different strategies to what would be appropriate for the treatment of an eating disorder</li> </ul>

Table 2: Summary of website intervention trial results\*

Result of intervention	Number of studies (reference numbers in brackets)		
	PA	Sedentary behaviour	Diet
<b>Significant improvement</b>	5 [42-44, 47, 48, 50]	2 [41, 44]	3 [42-44]

Website interventions					
Frenn et al, 2005, United States, Applied Nursing Research [42]	Quasi-experimental design  3 classes were allocated to intervention and 3 were allocated to control  Control participants had usual assignments	<ul style="list-style-type: none"> <li>Delivered via Blackboard.com during school time</li> <li>8 Nutrition education sessions</li> <li>4 video sessions</li> <li>Feedback based on stage of change</li> <li>Structured workbook to complement online content</li> </ul>	Set in an urban public middle school in the Midwest of America. Participants were 103 7 <sup>th</sup> grade students (age 12-14) in 6 classes. Most participants (70-75%) qualified for free lunch, and 70% were girls. About half of participants were Hispanic, 20% were Black, and the rest were White or another ethnicity.	<p><b>Diet</b></p> <p>Assessments were completed 1 week pre- and 1 week post-intervention. For dietary fat, 7 staging questions were asked.</p> <p>A Food habits questionnaire was used to measure percentage dietary fat. This includes a 21-item survey about various high-and low-fat food with a 5-option response</p> <p><b>Physical activity</b></p> <p>Assessments were completed 1 week pre- and 1 week post-intervention. Child and Adolescent Activity log was used to collect physical activity data.</p>	Only those who completed more than half of the sessions (3 sessions for diet and 2 sessions for PA) were included in the intervention group for analysis. Because data were treated this way, general linear model analysis was not possible, so t-tests were used.

<p><b>Williamson et al, 2005, United States, Eating and Weight Disorders – Studies on Anorexia, Bulimia and Obesity [68] AND</b></p> <p><b>Williamson et al, 2006, United States, Obesity [39]</b></p>	<p>Randomised controlled trial</p> <p>The control group received information, but no behavioural elements.</p>	<ul style="list-style-type: none"> <li>• Parent participation: Obese African American girls and one obese parent</li> <li>• Face-to-face counselling sessions and regular email contact with assigned counsellor. This was provided to both arms, but intervention participants received behavioural tasks in addition to information from counsellors.</li> <li>• Nutrition education</li> <li>• Online counselling</li> <li>• Online weight-monitoring graph</li> <li>• Physical activity graph</li> <li>• Links to targeted websites</li> <li>• Food monitoring with feedback</li> <li>• Behavioural contracting between adolescent, parent and counsellor</li> <li>• Problem solving element</li> <li>• Goal setting for specific behaviours</li> <li>• Television time self-monitoring</li> <li>• Quizzes</li> </ul>	<p>Participants were 57 overweight or obese African American girls and one obese parent. In every case but one, the parent was the girl's mother.</p> <p>Adolescents were aged 11-15 and the average parent age was 43.</p> <p>Average adolescent BMI was 36.4 and body fat % was 45.9 on average. Parents' values were 38.4 BMI and 48.4% fat on average.</p> <p>Participants were required to contribute \$300 toward the purchase of a new computer.</p>	<p><b>Diet</b></p> <p>Assessment completed at baseline, and months 6, 12, 18 and 24. Dietary assessment was conducted in the clinic, using a face-to-face questionnaire.</p> <hr/> <p><b>Physical activity</b></p> <p>Assessment completed at baseline, and months 6, 12, 18 and 24. The Weight Loss Behaviour Scale (WLBS) was completed online and used to assess behaviours.</p>	<p>ITT was used, according to last value carried forward methodology.</p> <p>ANCOVA was used to analyse change over time and baseline values were included as a covariate.</p>
<p><b>Jago et al, 2006, United States, Preventive Medicine [45]</b></p> <p><b>Thompson et al, 2009, United</b></p>	<p>Randomised controlled trial.</p> <p>Run in two waves: a Spring wave and an Autumn wave.</p>	<ul style="list-style-type: none"> <li>• Boy Scout badge programme where participants would receive a badge if they achieved 70% of possible points</li> <li>• Goal setting: one weekly logon to set a goal, and one</li> </ul>	<p>Trial run with boy scouts in Houston, TX.</p> <p>Participants were 473 10- to 14-year-old boy scouts from 42 troops.</p> <p>The majority of participants were White.</p>	<p><b>Physical activity</b></p> <p>Assessments completed at baseline, immediately post-intervention and 6 months post-</p>	<p>PA data were categorized into sedentary, light, and moderate to vigorous.</p> <p>Results were analysed using chi-square tests</p>

Author, publication year, country, journal	Study design	Intervention features	Setting and participants	Assessment	Analysis and confounding
<b>States, Preventive Medicine[46]</b>	One intervention arm received a physical activity intervention while the other received a mirror image fruit/vegetable intervention.	<ul style="list-style-type: none"> <li>to enter goal attainment</li> <li>• Problem solving component for those who did not reach their goals</li> <li>• Weekly animated comics</li> <li>• Knowledge game to increase logon rates</li> </ul>	Parental education was significantly associated with intervention group and wave.	<p>intervention.</p> <p>Physical activity was measured for 3 consecutive days at each time point using an accelerometer.</p> <p><b>Diet</b></p> <p>Fruit and vegetable consumption was measured using a modified FFQ and asked about consumption over the past 7 days.</p>	<p>and independent t tests. Repeated measures ANOVA using the Proc Mixed procedure was used to detect differences in physical activity over time between groups. Fixed effects included main effects for treatment group, visit time, wave and interactions within groups, visit time, and wave main effects.</p> <p>Analyses were run separately where either sedentary behaviour, light PA, MVPA, or counts per minute was the dependent variable.</p> <p>Diet was analysed using nested repeated measures to detect changes over time.</p> <p>Models were controlled for BMI, ethnicity and parental education.</p>
<b>Slootmaker et al, 2010, Netherlands,</b>	Randomised controlled trial.	<ul style="list-style-type: none"> <li>• Physical activity monitor (PAM)</li> <li>• Web-based advice based on</li> </ul>	Online intervention where participants were recruited in secondary schools in Amsterdam.	<p><b>Physical activity</b></p> <p>Assessed at baseline,</p>	<p>ITT was used.</p> <p>Linear regression</p>

Author, publication year, country, journal	Study design	Intervention features	Setting and participants	Assessment	Analysis and confounding
<b>Preventive Medicine [49]</b>	Control group received a single informational brochure with general physical activity advice.  The trial was run for 3 months.	12 initial questions on perceived barriers <ul style="list-style-type: none"> <li>• Exercise goal setting and PAM score monitoring</li> <li>• Activity log</li> <li>• Questionnaire about barriers and personalised feedback</li> <li>• Comparison to peers' scores</li> </ul>	Volunteers were aged 13-17 and the least active 50% were invited to participate.	end of 3-month intervention, and 5 months post-intervention.  The Activity Questionnaire for Adolescents and Adults was used to record physical activity in the last week of light, moderate and vigorous activity in metabolic equivalent (MET), as well as sedentary time.	analysis was used to test the differences between the intervention and control group at follow-up. Baseline values were included as covariates. Models were checked for effect modification by gender, and adjusted for programme adherence based on login frequency.
<b>De Bourdeaudhuij et al, 2010, Cities participating in HELENA (Vienna, Ghent, Heraklion, Dortmund, Athens and Stockholm), Journal of Adolescent Health [47]</b>  <b>AND</b>  <b>Cook et al, 2014, Cities participating in HELENA (see</b>	Quasi-experimental study where schools were randomised to intervention or control.  The intervention lasted 20 minutes and participants received the advice at baseline and 1 month.	<ul style="list-style-type: none"> <li>• Activ-o-meter</li> <li>• Diagnostic tool that collected demographic data, physical activity behaviours, and psychosocial determinants.</li> <li>• Tailored feedback based on diagnostic tool and readiness to change</li> <li>• Control participants received general advice</li> </ul>	<p>The intervention was completed in classrooms during school hours, but some teachers refused to allow class time, so these students were asked to complete the intervention at home.</p> <p>Participants were aged 12-17</p> <p>51% were boys</p> <p>47.6% were not complying with the recommended 60 minutes of moderate to vigorous physical activity per day at baseline.</p> <p>The trial was run in 6 different cities across Europe, so there was a wide range of demographic characteristics.</p>	<p><b>Physical activity</b></p> <p>Baseline, 1 month, and 3 months.</p> <p>Screening questionnaires the students filled in were used to collect data. PA levels were determined using an adolescent adaptation of the International Physical Activity Questionnaire, which asked for minutes of activity of different types.</p>	<p>Intention to treat: baseline observation carried forward.</p> <p>Linear mixed models with condition as between-subjects factor was used to analyse changes from baseline to 1 month. Gender was included as a factor in this model, and analyses were adjusted for baseline PA and age.</p> <p>This was repeated to assess longer term</p>

Author, publication year, country, journal	Study design	Intervention features	Setting and participants	Assessment	Analysis and confounding
above), Journal of School Health [48]					<p>changes at 3 months.</p> <p>All analyses were repeated using only those who did not meet the recommended 60 minutes per day MVPA at baseline.</p>
Maes et al, 2011, Cities participating in HELENA (see above), Public Health Nutrition [51]	Controlled trial (pilot evaluation). Not randomised.	<ul style="list-style-type: none"> <li>• FFQ used as a diagnostic tool</li> <li>• Computer-based tailored feedback based on FFQ</li> <li>• Assessed fibre, vitamin C, calcium, iron, fat and beverages</li> </ul>	<p>The intervention was completed as part of HELENA, in classrooms during school hours. Participants were aged 12-17.</p> <p>The trial was run in 2007.</p>	<p><b>Diet</b></p> <p>A short-term FFQ was completed at 1 month and medium term FFQ was completed at 3 months. FFQ was based on a validated computerized FFQ for fat intake, and further adapted to measure intake of target nutrients. Each country could include country-specific items.</p> <p>Results were analysed using a food composition database with 137 items.</p>	<p>Only those with complete data sets (data at each time point) were included in the analysis.</p> <p>Linear mixed models were used to analyse intervention effects on dietary measures. Condition was the between-subjects factor. Other factors included gender, and weight status.</p> <p>Adjusted for baseline intake and age.</p> <p>This was done for data from 1 month and 3 months.</p>

Author, publication year, country, journal	Study design	Intervention features	Setting and participants	Assessment	Analysis and confounding
<b>Chen et al, 2011, United States, Journal of Adolescent Health [43]</b>	Randomised controlled trial where Chinese American parent/adolescent pairs were randomised to intervention or control.  Run for 8 weeks	<ul style="list-style-type: none"> <li>Parent participation</li> <li>Targeted at Chinese American culture</li> </ul> <p>Adolescents' element:</p> <ul style="list-style-type: none"> <li>Weekly online sessions to increase self-efficacy</li> <li>Nutrition and physical activity education</li> <li>Coping skills</li> <li>Interactive food preparation software using common Chinese foods</li> <li>Goal setting</li> </ul> <p>Parents' element:</p> <ul style="list-style-type: none"> <li>3 short coaching sessions to build skills to support adolescents to improve their health</li> </ul> <p>Control participants accessed a website that provided general health advice</p>	<p>Internet intervention that could be accessed from any computer.</p> <p>Mean participant age was 12.5 (SD: 3.15) and all identified as Chinese or Chinese-American.</p> <p>Parents generally had a low acculturation score.</p> <p>1/3 of participating adolescents were overweight.</p>	<p><b>Diet</b></p> <p>Adolescents completed questionnaires at baseline, 2 months, 6 months, and 8 months after baseline assessment.</p> <p>A 3-day food diary was used to assess diet.</p> <hr/> <p><b>Physical activity</b></p> <p>Adolescents completed questionnaires at baseline, 2 months, 6 months, and 8 months after baseline assessment.</p> <p>A dual-mode actigraph was worn on the hip for 7 days, and the output was average counts in moderate and vigorous physical activity.</p>	<p>Linear mixed effects modelling was used to analyse change over time.</p> <p>T-tests were used to analyse differences between results at each follow up time point.</p>
<b>Ezendam et al, 2012, Netherlands, Archives of Paediatrics and Adolescent</b>	Cluster randomised controlled trial  Run for 10 weeks	<p>'FAT ain't PHAT'</p> <ul style="list-style-type: none"> <li>Eight 15-minute sessions</li> <li>Health information</li> <li>Behaviour assessment with individual feedback</li> <li>Option to formulate a</li> </ul>	<p>Set in schools in the Rotterdam area.</p> <p>Participants were 833 pupils aged 12-13. There were significant differences between groups with regards to gender and ethnicity.</p> <p>The intervention group had significantly more boys and the control group had significantly more participants of</p>	<p><b>Diet</b></p> <p>Assessments completed at baseline, 4 month follow-up, and 2 year follow-up.</p> <p>Food frequency</p>	<p>Intention to treat: baseline observation carried forward and last observation carried forward.</p> <p>Multilevel linear and</p>

Whittemore et al, 2012, United States, Journal of Adolescent Health [67]	Cluster RCT (clustered by class) to compare two school-based internet obesity prevention programmes.	HEALTH[e]TEEN <ul style="list-style-type: none"> <li>• Goal setting and progress tracking</li> <li>• Self-monitoring</li> <li>• Health coaching</li> <li>• Social networking</li> <li>• 8 interactive lessons on diet and physical activity</li> <li>• Encouraged to log diet and physical activities regularly</li> </ul> HEALTH[e]TEEN + coping skills training <ul style="list-style-type: none"> <li>• As above, with 4 additional sessions on coping skills</li> <li>• Social problem solving</li> <li>• Stress reduction</li> <li>• Assertive communication</li> <li>• Conflict resolution</li> </ul>	Set in three high schools in two cities in the north east of America.  384 pupils were recruited from biology classes at participating schools.  Participants were aged 14-17, with about 70% aged 14-15. 60% of participants were female, and 40% were overweight or obese.	<b>Diet</b>  Assessments were completed at baseline, 3 months and 6 months. Nutrition behaviour was measured with a 22-item survey. Key items were evaluated, and total scores were also calculated ranging from 0 (unhealthy) to 97 (healthy).	Mixed model analyses with autoregressive covariance for repeated data were used, including an ITT analysis. The analyses tested for time effect as well as group x time effect. Analyses were adjusted for age, gender, and race/ethnicity. Random effect of school or class was added to the model when it was significant.
				<b>Physical activity</b>  Assessments were completed at baseline, 3 months and 6 months.  Sedentary behaviour was measured using a validated questionnaire.  Physical activity was measured using the PA items from YRBS.	
Cullen et al, 2013, United States, Health Education Research [44]	Randomised controlled trial  Run for 8 weeks	Teen Choice: Food & Fitness <ul style="list-style-type: none"> <li>• Nutrition and physical activity information</li> <li>• Videos</li> <li>• Recipes</li> <li>• Access to a blog</li> <li>• Goal setting: one per week</li> </ul>	The trial was run in Houston, Texas.  Participants were 390 adolescents aged 12-17 with internet access.  70% were normal weight and 30% were overweight (>85 <sup>th</sup> percentile BMI for age and gender)	Assessments were completed immediately before the trial period and at the end of the trial period. (Week 1 and week 8)  Validated youth risk	One way analyses of covariance and logistic regression were conducted for each dependent variable, including all potential confounding (gender, age, race, SES, parent

Author, publication year, country, journal	Study design	Intervention features	Setting and participants	Assessment	Analysis and confounding
		Control participants received information and were asked to set a weekly goal		behaviour survey (YRBS) was used to collect data on diet and physical activity.	education level, numbers of children and adults at home, TV availability in child's bedroom and social desirability) as covariates.
<b>Patrick et al, 2013, United States, Journal of Diabetes Science and Technology [41]</b>	Randomised controlled trial with multiple interventions including a website.  The trial was run for 1 year	Website <ul style="list-style-type: none"> <li>• Parental involvement: adult version of the website</li> <li>• Stoplight approach to teach about diet and physical activity recommendations</li> <li>• Weekly goals, with related education and challenges</li> <li>• Skill building exercises</li> <li>• Rewards system</li> <li>• Assessment of progress (step count and weight tracking) and personalised feedback</li> <li>• Additional resources such as tips, recipes and tutorials</li> <li>• Website use was divided into 3 phases               <ul style="list-style-type: none"> <li>○ Phase 1 (weeks 1-17): education on healthy behaviours for weight loss</li> <li>○ Phase 2 (weeks 18-34): interactive components such as</li> </ul> </li> </ul>	The trial was run through a diabetes clinic in San Diego, California. Participants were aged 12-16 and at high risk for diabetes, but did not have diabetes. Average BMI was 97.6 <sup>th</sup> percentile for age and gender	<b>Diet</b>  Assessments were completed at baseline, 6 months, and at the end of the intervention (12 months).  Diet was assessed using the youth/adolescent FFQ (validated questionnaire for adolescents).	Mixed model analysis was used to test group effects at 12 months. The model used maximum likelihood repeated measures and ITT analysis was conducted. Analyses looked at the effect of treatment group as well as the interaction between treatment group and time.  Relative change scores were calculated as (12 month measure – baseline measure)/baseline measure. These were used in partial correlation analyses to test the correlations between change in

Lana et al, 2014, Spain and Mexico, Preventive Medicine [35]	Randomised controlled trial	Cancer prevention intervention called PREVCANADOL <ul style="list-style-type: none"><li>Adapted to school curriculum in each country – included problem solving</li><li>Emphasized the advantages of following recommendations and disadvantages of risky behaviours</li><li>Online social environment and peer forums</li><li>Videos</li><li>Links to further information</li><li>Skill building to avoid risk</li></ul> Those who provided a mobile phone number <ul style="list-style-type: none"><li>Weekly text messages to encourage healthy behaviours</li></ul>	Set in secondary schools in Spain and Mexico.				<b>Diet</b>  Assessments were completed at baseline and at the end of the academic year. The study focused on various cancer risk behaviours. Food was assessed using a validated FFQ.  <b>Physical activity</b>  Assessments were completed at baseline and post-intervention. Sedentary behaviour was assessed, but details of this tool are not provided.	Students completed a cancer risk questionnaire which assessed smoking, diet, alcohol, sedentary behaviours and sun exposure. These factors were scored separately, and used to come up with a final risk score.  Changes in risky behaviours were analysed using McNemar’s and Wilcoxon’s tests. Then GLM was used to test for association between changes in behaviour and group allocation.  Logistic regression was performed to assess OR for giving up risky behaviours at post-test according to study group.  Binary logistic regression was used to assess whether there was a difference in

Table 4: Findings from included studies

Author, publication year, country, journal	Participants		Main findings	Conclusion	Risk of bias
	Sample size and follow-up	Engagement with interventions			
Website interventions					
Frenn et al, 2005, United States, Applied Nursing Research[42]	103 participants	No data reported	<b>Diet</b>	This intervention delivered via Blackboard.com showed favourable results with regards to physical activity and dietary fat consumption amongst Midwestern middle school students.	High
	77% follow-up		Those participating in more than half the sessions decreased dietary fat from 30.7% to 29.9% (p=0.008) Control participants showed no change (31.5% vs 31.6%) The 6 students who received less than half of the dietary sessions were not significantly different from the control participants (0.08)		
			<b>Physical activity</b>		
			Intervention students who completed more than half of sessions increased MVPA by an average of 22 minutes, compared with a decrease of 46 min in the control group (p=0.05).		
			Those who completed all three sessions increased activity by 33 minutes.		
Williamson et al, 2005, United States, Eating and Weight Disorders – Studies on Anorexia, Bulimia and Obesity[73] AND Williamson et al, 2006, United States, Obesity[39]	Intervention n=28	For all weight loss behaviours, baseline values were a significant covariate.	<b>Diet</b>	Compared to the passive intervention, the behavioural intervention showed a greater improvement in physical activity and diet amongst very overweight and obese African-American girls. However, the changes were not sustained at 24 months.	Medium
	Control n=29		At 12 months: The intervention participants showed a significant decrease in energy intake while control participants did not. However, participants in the control group showed a significant decrease in overeating while intervention participants did not.		
	70% follow-up	Intervention arm had significantly more hits on the website than control.	At 24 months: Participants in both groups showed a significant decrease in overeating (p<0.05), although the control group showed a greater improvement.		
		Parent and adolescent use of	Participants in the behavioural group ate less fattening foods than the control group (p<0.05) at 12 months and 18 months, but not at 24 months.		

Author, publication year, country, journal	Participants		Main findings	Conclusion	Risk of bias											
	Sample size and follow-up	Engagement with interventions														
		the website were significantly correlated.  Within the intervention group, change in body fat was negatively correlated with email submissions, percent correct answers on quizzes and use of weight graph component.	<b>Physical activity</b>  In both groups, adolescents showed significant improvement in physical activity from baseline (p<0.05) with control participants showing a larger improvement at 18 months, but both groups being similar at other time points.													
Jago et al, 2006, United States, Preventive Medicine[45]	Physical activity n=240  Diet n=233	44% of those whose parents had college education	<b>Diet</b>  There was a significant group x time interaction for fruit juice consumption at 1 month post-intervention only.	The internet intervention resulted in a small but significant increase in light physical activity among the spring participants, but not the autumn participants.	Medium											
Thompson et al, 2009, United States, Preventive Medicine[46]	88% follow-up	provided data at both time points compared to 27% of those whose parents did not.	There was also a significant group x time x wave interaction for low-fat vegetable consumption from baseline to 6 months post-intervention.  Results presented as M(SE)	The authors suggest that this could be due to seasonality in children’s physical activity behaviours, especially in a hot climate.

### Baseline to 3 months

In the total sample, there was a condition x gender effect for vigorous activity in leisure time

$\beta$ = -55.06 (24.45).

There were significant condition effects for cycling for transportation, walking in leisure time, moderate activity in leisure time, vigorous activity in leisure time, and total MVPA.

Lana et al, 2014, Spain and Mexico, Preventive Medicine[35]	Control n=987	Factors that increased the odds of completing the trial included being Mexican, mothers having a university degree, and high self-efficacy.  Factors associated with dropping out were being 15 or older and having relatives or friends who smoked.	<b>Diet</b>  In all three groups (comparison, internet, and internet + text) the percentage of participants who did not eat the recommended amount of fruit per day decreased significantly ( $p<0.001$ ).  Control decreased by 66.8%  Internet group decreased by 62.6%  Internet + text group decreased by 71.5%  Vegetable and fat intake did not change in any groups.	Various analyses were performed to assess change in cancer risk behaviours, and some significant results were found. However, the only dietary/physical activity result was found in consumption of fruit, which changed significantly in the control group as well as the intervention groups. Therefore, the intervention did not appear to have any significant effects on any dietary or physical activity behaviours.	High
	Intervention n=1014		<b>Physical activity</b>  There were no significant effects in any group for sedentary behaviour.		
	37% follow-up				
Guthrie et al, 2015, United States, PLOS ONE[50]	Passive control n=59	Participants wore accelerometers on 63% of study days regardless of group. 82% of intervention participants visited the website at least once.  Median incentive earned was \$5	Over the 6 week period, there was a significant difference between groups in average MVPA duration ( $p<0.0001$ ).  Over the course of the study:  Passive control group did an average of 10.27 min/day  Active control group averaged 9.12 min/day  Intervention group averaged 15.26 min/day  These results did not significantly differ over time.	Over a 6-week period, using the pedometer and website that included feedback and a reward system, led to a physical activity level that was approximately 50% higher than those not using the intervention.	Low

### Results for girls

\*p<0.05

Author, publication year, country, journal	Participants		Main findings	Conclusion	Risk of bias	
	Sample size and follow-up	Engagement with interventions				
Lubans et al, 2010, Australia, BMC Public Health[62] AND Lubans et al, 2012, Australia, Archives of Pediatrics and Adolescent Medicine[72] AND Dewar et al, 2014, Australia, Journal of Science and Medicine in Sport[63]	Intervention n=148	<u>Average attendance</u>	There were no significant changes in any dietary, physical activity or sedentary behaviours at 1 year.	NEAT girls, which was a school-based multi-component intervention that included a text messaging element, did not result in any significant changes in diet or physical activity.	Medium	
	Control n=179	School sport sessions: 60.6%				
	80% follow-up	Nutrition workshops: 65%				
		Optional lunchtime sessions: 24.6%				
		On average, participants completed 8.8% of home challenges.				
	No process data on text messaging element.					
Smith et al, 2014, Australia, Pediatrics [65]	Intervention n=181	65% of boys attended more than 70% of sport sessions	<b>Diet</b>  Intervention boys significantly decreased their sweetened beverage consumption compared to control boys.	70% of participants had smartphones and 63% reported using the app.	Medium	
	Control n=180	44% attended at least 2/3 of lunchtime sessions				
	80% follow-up	70% of boys				

Author, publication year, country, journal	Participants		Main findings							Conclusion	Risk of bias
	Sample size and follow-up	Engagement with interventions									
		owned a smartphone or tablet and 63% reported using the ATLAS app.	Intervention								amongst boys from deprived backgrounds.
			Control	3.9±0.40	3.1±0.41	-0.8±0.19	<0.001				
				3.9±0.36	3.7±0.36	-0.1±0.18	<0.001	5.7±.067	.01		
		Of those who owned a smartphone, 70% reported using the goal setting function, 62% used the technique monitoring function, 49% used step tracking and 49% used the fitness challenge feature.									
		Half of the group agreed that the push prompt was a useful reminder and 44% agreed that the app was enjoyable to use. However, 95% agreed that the ATLAS programme as a whole was enjoyable.									
			<b>Physical activity</b>								
			There were no improvements in physical activity, although boys in the intervention group reported less screen time at follow-up.								
			Physical activity outcomes presented at mean ± SE. Models were adjusted for school clustering and participant socioeconomic status								
			Outcome	Baseline	8 Months	Change	P value	Adjusted difference in change	P value

<hr/>					
			<b>Physical activity</b>		
			There were no significant changes in hours of exercise per week.		
			Intervention group		
			Baseline: 17.38 hours		
			Follow-up: 12.31 hours		
			Control group		
			Baseline: 16.74 hours		
			Follow-up: 12.6 hours		
<hr/>					
Social media intervention					
Wojcicki et al, 2014, United States, JMIR Research Protocols [60]	Behavioural n=10	80% of daily posts were viewed by all participants, but engagement with posts (likes, comments, shares) was low at 26.7% of posts.	<b>Physical activity</b>	While there was a significant increase in self-reported leisure activity, there was no change in objectively measured total physical activity as a result of this Facebook intervention.	Low
	Informational n=11		There were significant (p=0.009) improvements in self-reported physical activity over time, but there was no group x time interaction. There were no significant results for objectively measured physical activity or for self-reported sedentary behaviours in either group.		
	95% follow-up

## Cochrane Central Register of Controlled Trials (CENTRAL)

Searched via the Cochrane Library 20<sup>th</sup> October 2015

- #1 MeSH descriptor: [Cell Phones] explode all trees
- #2 MeSH descriptor: [Text Messaging] this term only
- #3 MeSH descriptor: [Reminder Systems] this term only

#4 MeSH descriptor: [Internet] this term only

#5 MeSH descriptor: [Social Media] this term only

#6 MeSH descriptor: [Mobile Applications] this term only

#7 MeSH descriptor: [Computers, Handheld] this term only

#8 MeSH descriptor: [Software] this term only

#9 MeSH descriptor: [Electronic Mail] this term only

#10 MeSH descriptor: [Video Games] this term only

#11 MeSH descriptor: [Social Networking] this term only

#12 #1 or #2 or #3 or #4 or #5 or #6 or #7 or #8 or #9 or #10 or #11

#13 ((digital or email or e-mail or telephone or phone or web or internet or online or electronic) near/2 intervention\*):ti,ab,kw (Word variations have been searched)

#14 ("text messag\*" or SMS or "short messag\* service\*" or texting or messaging):ti,ab,kw (Word variations have been searched)

#15 ("mobile phone\*" or "cell phone\*" or cellphone\* or "smart phone\*" or smartphone\*):ti,ab,kw (Word variations have been searched)

#16 ("mobile health" or "mobile technolog\*" or mhealth):ti,ab,kw (Word variations have been searched)

#17 (email or e-mail or "electronic mail" or "electronic reminder\*"):ti,ab,kw (Word variations have been searched)

#18 ("new media" or "social media" or "electronic media"):ti,ab,kw (Word variations have been searched)

#19 ((phone\* or smartphone\* or cellphone\* or mobile\* or web\* or internet) near/2 (app or apps or application\*)):ti,ab,kw (Word variations have been searched)

#20 (facebook or twitter or instagram or "social networking"):ti,ab,kw (Word variations have been searched)

#21 (internet or website\* or "web site\*"):ti,ab,kw (Word variations have been searched)

#22 (laptop\* or PDA\* or "personal digital assistant\*"):ti,ab,kw (Word variations have been searched)

#23 (video next (game or games or gaming)):ti,ab,kw (Word variations have been searched)

#24 #13 or #14 or #15 or #16 or #17 or #18 or #19 or #20 or #21 or #22 or #23

#25 #12 or #24

#26 MeSH descriptor: [Adolescent] this term only

#27 adolescen\*:ti,ab,kw or teen or teens or teenager\*:ti,ab,kw or preteen or pre-teen\* or preteens or pre-teens or preteenager\* or pre-teenager\*:ti,ab,kw or youth or youths:ti,ab,kw or "young people" or "young person\*":ti,ab,kw (Word variations have been searched)

#28 #26 or #27

#29 MeSH descriptor: [Diet] explode all trees

#30 MeSH descriptor: [Feeding Behavior] explode all trees

#31 MeSH descriptor: [Vitamins] explode all trees

#32 MeSH descriptor: [Vitamin A] this term only

#33 MeSH descriptor: [Ascorbic Acid] this term only

#34 MeSH descriptor: [Vitamin D] this term only

#35 MeSH descriptor: [Vitamin B 6] this term only

#36 MeSH descriptor: [Dietary Fats] this term only

#37 MeSH descriptor: [Dietary Proteins] this term only

#38 MeSH descriptor: [Dietary Carbohydrates] this term only

#39 MeSH descriptor: [Dietary Fiber] this term only

#40 MeSH descriptor: [Iron, Dietary] this term only

#41 MeSH descriptor: [Calcium, Dietary] this term only

#42 MeSH descriptor: [Fruit] this term only

#43 MeSH descriptor: [Vegetables] this term only

#44 #29 or #30 or #31 or #32 or 5 or #34 or #35 or #36 or #37 or #38 or #39 or #40 or #41 or #42 or #43

#45 (diet\* or food or nutrition):ti,ab,kw (Word variations have been searched)

#46 ((healthy or balanced) near/2 (diet\* or eating)):ti,ab,kw (Word variations have been searched)

#47 (fruit\* near/2 (intake or consum\* or increase or portion\* or serving\* or frequenc\* or number\* or preference\* or choice\*)):ti,ab,kw (Word variations have been searched)

#48 (vegetable\* near/2 (intake or consum\* or increase or portion\* or serving\* or frequenc\* or number\* or preference\* or choice\*)):ti,ab,kw (Word variations have been searched)

#49 "5 a day":ti,ab,kw or "five a day":ti,ab,kw (Word variations have been searched)

#50 (food next (choice\* or frequenc\*)):ti,ab,kw (Word variations have been searched)

#51 ((increas\* or improv\* or encourag\* or promot\* or recommend\* or motivat\* or incentiv\* or market\* or advert\*) near/3 (iron or calcium or fibre or carbohydrates or protein\*)):ti,ab,kw (Word variations have been searched)

#52 ((increas\* or improv\* or encourag\* or promot\* or recommend\* or motivat\* or incentiv\* or market\* or advert\*) near/3 vitamin\*)):ti,ab,kw (Word variations have been searched)

#53 ((increas\* or improv\* or encourag\* or promot\* or recommend\* or motivat\* or incentiv\* or market\* or advert\*) near/3 ("healthy eating")):ti,ab,kw (Word variations have been searched)

#54 ((increas\* or improv\* or encourag\* or promot\* or recommend\* or motivat\* or incentiv\* or market\* or advert\*) near/3 ("healthy diet\*")):ti,ab,kw (Word variations have been searched)

#55 ((increas\* or improv\* or encourag\* or promot\* or recommend\* or motivat\* or incentiv\* or market\* or advert\*) near/3 ("balanced diet\*")):ti,ab,kw (Word variations have been searched)

#56 ((increas\* or improv\* or encourag\* or promot\* or recommend\* or motivat\* or incentiv\* or market\* or advert\*) near/3 (fruit\* or vegetable\*)):ti,ab,kw (Word variations have been searched)

#57 ((increas\* or improv\* or encourag\* or promot\* or recommend\* or motivat\* or incentiv\* or market\* or advert\*) near/3 (micronutrient\* or macronutrient\* or nutrient\*)):ti,ab,kw (Word variations have been searched)

#58 #45 or #46 or #47 or #48 or #49 or #50 or #51 or #52 or #53 or #54 or #55 or #56 or #57

#59 #44 or #58

#60 MeSH descriptor: [Exercise] explode all trees

#61 MeSH descriptor: [Recreation] explode all trees

#62 MeSH descriptor: [Exercise Therapy] explode all trees

#63 MeSH descriptor: [Physical Fitness] this term only

#64 MeSH descriptor: [Running] this term only

#65 MeSH descriptor: [Jogging] this term only

#66 MeSH descriptor: [Walking] this term only

#67 MeSH descriptor: [Swimming] this term only

#68 (physical near/3 (fit\* or train\* or activ\* or endur\*)):ti,ab,kw (Word variations have been searched)

#69 (exercis\* near/3 (fit\* or train\* or activ\* or endur\*)):ti,ab,kw (Word variations have been searched)

#70 ((promot\* or uptak\* or encourag\* or increas\* or start\* or adher\*) near/3 (exercis\* or gym\* or sport\* or fitness)):ti,ab,kw (Word variations have been searched)

#71 ((decreas\* or reduc\* or discourag\*) near/3 (sedentary or deskbound)):ti,ab,kw (Word variations have been searched)

#72 (sport\* or walk\* or running or jogging or bicycling or biking or swimming):ti,ab,kw (Word variations have been searched)

#73 #60 or #61 or #62 or #63 or #64 or #65 or #66 or #67 or #68 or #69 or #70 or #71 or #72

#74 MeSH descriptor: [Obesity] explode all trees

#75 MeSH descriptor: [Overweight] this term only

#76 MeSH descriptor: [Weight Reduction Programs] this term only

#77 (obesity or obese or overweight):ti,ab,kw (Word variations have been searched)

#78 (weight near/2 (loss or losing or lost or reduc\* or maintenance or maintain\* or manag\*)):ti,ab,kw (Word variations have been searched)

#79 #74 or #75 or #76 or #77 or #78

#80 #25 and #28 and (#59 or #73)

#81 #25 and #28 and #79

#82 #80 or #81

## Appendix C: Quality scoring rubric

Item	Risk of bias		
	Low (+1)	Medium (0)	High (-1)
Study design	Randomised controlled trial	Quasi-experimental studies that include a control group	Experimental studies that do not use a control group.
Randomisation	Random numbers table or computer randomisation	Randomised by methods other than random number table, or randomised in large clusters.	Not randomised, or inadequate randomisation methods such as birth date used. OR randomisation methods not described
Blinding	Participants and analysts were blinded to treatment condition.	Participants were not sufficiently blinded, but analysis of results was blinded.	No blinding, or insufficient blinding methods.
Were groups similar at baseline?	Appropriate statistical tests (chi-square and/or t-tests) used to analyse differences between groups at baseline, and found that there were no significant differences.	Groups are similar, but there are some differences that are judged to be acceptable.	Analyst did not test for differences at baseline, or there were significant differences between groups.
Selection	Participants were randomly selected.	School based interventions that require pupil/parental consent.	Volunteers are recruited.
Loss to follow-up	Loss to follow up of less than 10% AND similar loss in all groups.	More drop outs than expected (10%-30%). Similar loss between groups.	High dropout rate (>30%) and/or significant difference in follow up between groups.
Dietary assessment	Very reliable methodology that does not rely on self-report	Measures are reliable, but self-reported	Unreliable methods including questionnaires that have not been piloted or validated, and methods that increase the likelihood of socially acceptable responses
Physical activity assessment	Very reliable methodology that does not rely on self-report	Measures are reliable, but self-reported	Unreliable methods including questionnaires that have not been piloted or validated, and methods that increase the likelihood of socially acceptable responses
Performance bias	The intervention was delivered in a way that was not variable eg. Computer-generated.	The intervention was probably delivered consistently. Eg. The same person delivering a lesson to multiple groups.	The intervention was likely have been delivered differently across the trial. Eg. Asking teachers to add elements to their curriculum without further training.
Intention to treat	Intention to treat analysis was clearly used		Intention to treat was not used, or not stated
Analytic methods	Statistical tests used are rigorous and appropriate for the data set. (Regression modelling, ANOVA, etc)	Statistical methods are effective, but not as rigorous as they could be.	Statistical methods are limited, and only report descriptive stats OR tests used are not appropriate for the dataset.

<p>Did the analysis adjust for confounding?</p> <ul style="list-style-type: none"><li>• Educational attainment or SES</li><li>• BMI/weight</li><li>• Gender</li><li>• Age</li><li>• Baseline behaviour</li></ul>	<p>The statistical model used adjusts for all relevant confounding factors.</p>	<p>The model adjusts for 3 or 4 confounders.</p>	<p>The analysis adjusts for fewer than 3 confounders</p>
